```

Train Test Split

```
In [4]:
```

```
from sklearn.model_selection import train_test_split
train_x, test_x, train_y, test_y = train_test_split(x,y, random_state = 9)
train_x.shape, test_x.shape, train_y.shape, test_y.shape
```

Out[4]:

```
((6392, 45), (2131, 45), (6392,), (2131,))
```

Implementing Linear Regression

In [5]:

```
from sklearn.linear_model import LinearRegression as LR from sklearn.metrics import mean_absolute_error as mae
```

In [6]:

Out[6]:

LinearRegression()

predicting over Training Set

In [7]:

```
train_pred = lr.predict(train_x)
train_mae = mae(train_pred, train_y)
print('Training Mean Absolute Error :', train_mae)
```

Training Mean Absolute Error: 827.3664175128886

predicting over Test Set

In [8]:

```
test_pred = lr.predict(test_x)
test_mae = mae(test_pred, test_y)
print('Test Mean Absolute Error :', test_mae)
```

Test Mean Absolute Error: 861.806594100068

Parameters of Linear Regression

In [9]:

```
1 # coefficients of the equation
2 lr.coef_
```

Out[9]:

```
array([ -1.13512756, -179.79233388, 15.65668767, -18.6574453, 4.26675415, 4.2154459, 43.9152877, 20.49224006, -72.8897278, -22.38153707, -1.17784843, -91.0598699, -15.79938771, -39.47904273, -22.75735283, 8.6798061, -52.75260518, -20.67316491, -20.45574445, 19.09990758, 29.94212896, 268.66029346, -41.52897269, -46.52031544, 48.20370526, -495.50373377, -46.06491435, 158.18888447, -38.63257523, -468.75193706, 595.48427957, 143.00628086, -89.44056066, 309.29119287, -67.57691129, -46.06491435, 489.27479304, -16.45446332, -227.03765548, 211.75459927, 15.28305621, -964.25567083, 407.4039665, -38.63257523, 595.48427957])
```

In [20]:

```
feature_importance_df = pd.DataFrame({
    'Feature' : train_x.columns,
    'Importance': lr.coef_
}

feature_importance_df['Importance_magnitude'] = feature_importance_df.Importance.abs()

feature_importance_df.sort_values(by='Importance_magnitude', inplace=True, ascending=False)
    # sorting so we can plot only top n important features for better visibility

feature_importance_df.head()
```

Out[20]:

Feature Importance Importance_magnitude

41	Outlet_Type_Grocery Store	-964.255671	964.255671
44	Outlet_Type_Supermarket Type3	595.484280	595.484280
30	Outlet_Identifier_OUT027	595.484280	595.484280
25	Outlet_Identifier_OUT010	-495.503734	495.503734
36	Outlet Size Medium	489.274793	489.274793

In [23]:

```
# plotting the coefficients

plt.figure(figsize=(5,3), dpi=120, facecolor='w', edgecolor='b')

x = feature_importance_df['Feature'].head(20)

y = feature_importance_df['Importance'].head(20)

plt.bar( x, y )

plt.xlabel( "Variables")

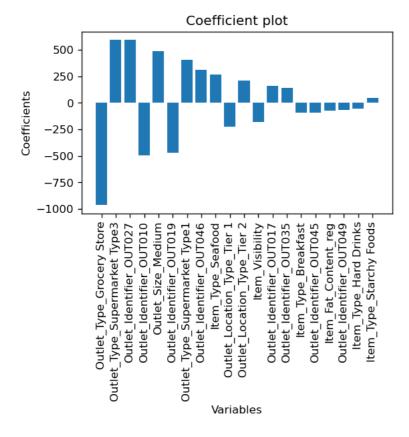

plt.ylabel('Coefficients')

plt.xticks(rotation=90)

plt.title('Coefficient plot')
```

Out[23]:

Text(0.5, 1.0, 'Coefficient plot')

Note: Here we can see that the model depends upon some Independent variables toos much, But these coefficients are not suitable for interpretation because these are not scaled, we will look into this later on in details.

Validiating Assumptions of Linear Regression

```
In [11]:
```

```
# Calculating Error Terms

2
3    error_df = pd.DataFrame({
        'original_values' : test_y,
        'predicted_values': test_pred
}

6    error_df['error'] = error_df['original_values'] - error_df['predicted_values']

9    error_df.head()
```

Out[11]:

	original_values	predicted_values	error
2344	1095.2410	3460.817769	-2365.576769
4005	5070.7328	3000.322073	2070.410727
2897	892.1720	712.864464	179.307536
6252	2976.1260	3200.235119	-224.109119
6414	365.5242	1956.201769	-1590.677569

Homoscedasticity: Constant Vairance of Error Terms

In [12]:

```
plt.figure(figsize=(9,3), dpi=120, facecolor='w', edgecolor='b')

f = range(0,2131)

k = [0 for i in range(0,2131)]

plt.scatter( f, error_df.error, label = 'residuals')

plt.plot( f, k , color = 'red', label = 'regression line' )

plt.xlabel('fitted points ')

plt.ylabel('residuals')

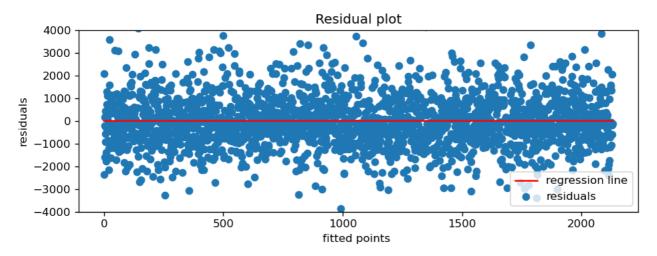

plt.ylabel('residual plot')

plt.ylim(-4000, 4000)

plt.legend()
```

Out[12]:

<matplotlib.legend.Legend at 0x1a7cd95b400>

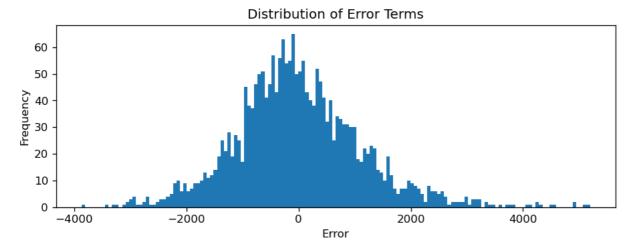

The Residual plot clearly Looks Homoscedastic, i.e. the the variance of the error across the dataset is nearly constant.

Normally Distributed Error Terms

In [13]:

```
# Histogram for distribution of error terms
plt.figure(figsize=(9,3), dpi=120, facecolor='w', edgecolor='b')
plt.hist(error_df.error, bins = 150)
plt.xlabel('Error')
plt.ylabel('Frequency')
plt.title('Distribution of Error Terms')
plt.show()
```

According to the Histogram, the distribution of error is nearly normal, But there are some outliers on the Higher end of the errors which could be handled easily.

Another way to check normal distribution is Q-Q Plot

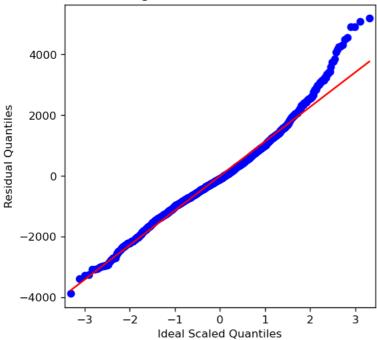

In [14]:

```
# importing the QQ-plot from the from the statsmodels
import numpy as np
from statsmodels.graphics.gofplots import qqplot

## Plotting the QQ plot
fig, ax = plt.subplots(figsize=(5,5) , dpi = 120)
qqplot(error_df.error, line = 's' , ax = ax)
plt.ylabel('Residual Quantiles')
plt.xlabel('Ideal Scaled Quantiles')
plt.title('Checking distribution of Residual Errors')
plt.show()
```

C:\Users\rkt7k\anaconda3\lib\site-packages\statsmodels\graphics\gofplots.py:993: UserWarning: marker is redundantly defined
by the 'marker' keyword argument and the fmt string "bo" (-> marker='o'). The keyword argument will take precedence.
ax.plot(x, y, fmt, **plot_style)

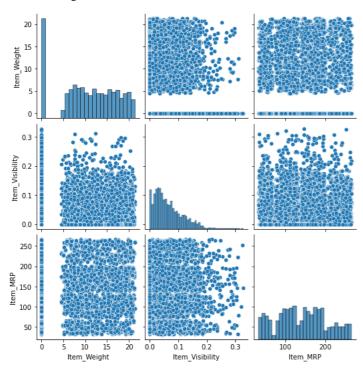

The QQ-plot clearly verifies our findings from the the histogram of the residuals, the data is mostly normal in nature, but there sre some outliers on the higher end of the Residues.

In [15]:

```
import seaborn as sns
sns.pairplot(df[['Item_Weight', 'Item_Visibility', 'Item_MRP']])
```

Out[15]:

<seaborn.axisgrid.PairGrid at 0x1a7d0480700>

Since there are lot of features and feature selection is not in the scope of this notebook, displayed pairplot only between some columns.

Variance Inflation Factor (VIF) (Checking for multi collinearity)

In [25]:

```
# Importing Variance_inflation_Factor funtion from the Statsmodels
from statsmodels.stats.outliers_influence import variance_inflation_factor
from statsmodels.tools.tools import add_constant
```

In [32]:

```
trainx_with_constant = add_constant(train_x.values)
trainx_with_constant[1]
# we can observe, one has beed added as the first value
```

Out[32]:

```
In [34]:
```

```
1 # Calculating VIF for every column (only works for the not Catagorical)
   VIF= pd.Series([variance_inflation_factor(trainx_with_constant, i) for i in range(1,trainx_with_constant.shape[1])],
 2
                    index =train_x.columns)
 3
 4 VIF
C:\Users\rkt7k\anaconda3\lib\site-packages\statsmodels\stats\outliers_influence.py:193: RuntimeWarning: divide by zero enco
```

untered in double_scalars vif = 1. / (1. - r_squared_i)

```

                                          inf
Outlet_Type_Supermarket Type1
                                          inf
```

```
1 note:
 vif = 1 / (1-R2)
3 so if R2 value is coming 1, the vif will be infinity
_{\mathrm{5}} but why VIF here is infinity, if we see closely, INF is only for the ONE HOT ENCODED variables
  so what happens is, when we encode all n categories, then if (n-1) categories is 0, it means that that last nth category is 1, so
6
  actually we dont need to encode all n categories and rather encode only (n-1) categories.
8
  Here as all n categories are encoded, the (n-1) features could be easily used to predict that last nth feature and hence R2 for that
  is 1
```

Model Inpretability

Outlet_Type_Supermarket Type2

Outlet_Type_Supermarket Type3

dtype: float64

So far we have simply been predicting the values using the linear regression, But in order to Interpret the model, the normalising of the data is essential.

```
In [40]:
```

```
1 lr = LR(normalize=True)
2 lr.fit(train_x, train_y)
```

Out[40]:

LinearRegression(normalize=True)

inf

inf

In [41]:

```
train_pred = lr.predict(train_x)
train_mae = mae(train_pred, train_y)
print('Training Mean Absolute Error :', train_mae)
```

Training Mean Absolute Error: 850.426924968711

In [42]:

```
test_pred = lr.predict(test_x)
test_mae = mae(test_pred, test_y)
print('Training Mean Absolute Error :', test_mae)
```

Training Mean Absolute Error: 880.1328247770999

In [43]:

```
feature_importance_df = pd.DataFrame({
    'Feature' : train_x.columns,
    'Importance': lr.coef_
}

feature_importance_df['Importance_magnitude'] = feature_importance_df.Importance.abs()

feature_importance_df.sort_values(by='Importance_magnitude', inplace=True, ascending=False)

sorting so we can plot only top n important features for better visibility

feature_importance_df.head()
```

Out[43]:

	Feature	Importance	Importance_magnitude
29	Outlet_Identifier_OUT019	-9.311582e+15	9.311582e+15
26	Outlet_Identifier_OUT013	-7.190359e+15	7.190359e+15
35	Outlet_Size_High	-6.300353e+15	6.300353e+15
44	Outlet_Type_Supermarket Type3	-6.171283e+15	6.171283e+15
43	Outlet_Type_Supermarket Type2	6.060654e+15	6.060654e+15

In [44]:

```
# plotting the coefficients

plt.figure(figsize=(5,3), dpi=120, facecolor='w', edgecolor='b')

x = feature_importance_df['Feature'].head(20)

y = feature_importance_df['Importance'].head(20)

plt.bar( x, y )

plt.xlabel( "Variables")

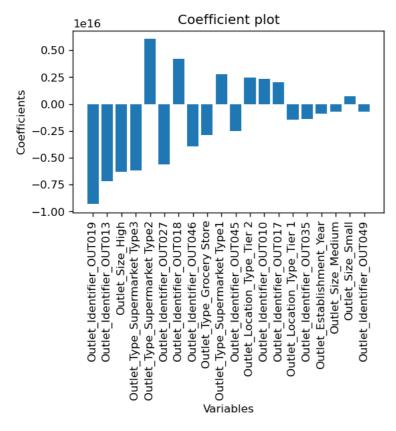

plt.ylabel('Coefficients')

plt.xticks(rotation=90)

11 plt.title('Coefficient plot')
```

Out[44]:

Text(0.5, 1.0, 'Coefficient plot')

Now the coefficients we see are normalised and we can easily make final inferences out of it.
